Abstract—Insert abstract here.

I. INTRODUCTION

This project is focused on applying matching theory to a virtual machine job assignment problem.

II. RELATED WORK

Most similar topics: VM Cosheduling and VM Migration papers.

Related to VM Coscheduling: Distributed Selfish Load Balancing

Related to VM Migration: Seen As Stable Marriage and Online VM Shuffling (continuation of VM Migration work).

III. METHOD DESCRIPTION

High level description if needed.

A. Problem Formulation

The problem this paper is exploring is how to optimize job assignment to separate computer clusters. Each of these jobs perform differently on different cores types. These core types can be graphical processors, computational processors, or something else. Each of these clusters have different core types. Each job can only be divided into a finite number of threads, and each job is assigned to one computer at a time.

(probably a good place to introduce matching theory and the college admissions game). This problem can be formed as a college admissions game. The differences are that the institutions have multiple quotas, each applicant can fill multiple slots of different types, applicants prefer different slot types over others, and an applicant cannot be divided among multiple institutions.

Key assumptions for this problem are: the virtual machines will be treated like flexible computers, jobs are submitted at the same time, chosen jobs are completed simulatenously, unchosen jobs will be submitted with the next round, no indifference, and no externalities.

B. Proposed Algorithm

Things to do: Write the math and assumptions, state why we are doing this, and show that this will be stable as well.

IV. RESULTS AND DISCUSSION

Show results and discuss what they represent.

V. CONCLUSION

The conclusion goes here.

VI. FUTURE WORK

List possible future work here.

VII. INDIVIDUAL CONTRIBUTIONS

Enumerated individual contributions.

ACKNOWLEDGMENT

The authors would like to thank...
